

# Microwave Wideband Synthesizer with Integrated VCO

## FEATURES

- ▶ Fundamental VCO frequency range: 10 GHz to 20 GHz
- ▶ VCO phase noise improvement of up to 3 dB as compared to ADF4382
- ▶ Integrated RMS jitter at 20 GHz = 18 fs (integration bandwidth: 100 Hz to 100 MHz)
- ▶ Integrated RMS jitter at 20 GHz = 31 fs (ADC SNR method)
- ▶ VCO fast calibration time: <2  $\mu$ s
- ▶ VCO autocalibration time: <100  $\mu$ s
- ▶ Phase noise floor: -156 dBc/Hz at 20 GHz
- ▶ PLL specifications
  - ▶ -239 dBc/Hz: normalized in-band phase noise floor (integer mode)
  - ▶ -287 dBc/Hz: normalized 1/f phase noise floor
  - ▶ 625 MHz maximum phase/frequency detector input frequency
  - ▶ 4.5 GHz reference input frequency
  - ▶ Typical spurious  $f_{PFD}$ : -90 dBc
- ▶ Reference to output delay specifications
  - ▶ Propagation delay temperature coefficient: 0.06 ps/°C
  - ▶ Adjustment step size: <1 ps
- ▶ Multichip output phase alignment
- ▶ 3.3 V and 5 V power supplies
- ▶ ADIsimPLL™ loop filter design tool support
- ▶ 7 mm × 7 mm, 48-terminal LGA
- ▶ -40°C to +105°C operating temperature

## APPLICATIONS

- ▶ High performance data converter clocking
- ▶ Wireless infrastructure (MC-GSM, 5G, 6G)
- ▶ Test and measurement

## GENERAL DESCRIPTION

The ADF4383 is a high performance, ultra-low jitter, fractional-N phased-locked loop (PLL) with an integrated voltage controlled oscillator (VCO) ideally suited for local oscillator (LO) generation for 5G applications or data converter clock applications. The high performance PLL has a figure of merit of -239 dBc/Hz, low 1/f noise and high PFD frequency of 625 MHz in integer mode that can achieve ultra-low in-band noise and integrated jitter. The ADF4383 can generate frequencies in a fundamental octave range of 10 GHz to 20 GHz, thereby eliminating the need for subharmonic filters. The output dividers on the ADF4383 allows a complete output frequency range to be generated from 625 MHz to 20 GHz.

For multiple data converter clock applications, the ADF4383 automatically aligns its output to the input reference edge by including the output divider in the PLL feedback loop. For applications that require deterministic delay or delay adjustment capability, a programmable reference to output delay with <1 ps resolution is provided. The reference to output delay matching across multiple devices and over temperature allows predictable and precise multichip alignment.

The simplicity of the ADF4383 block diagram eases development time with a simplified serial peripheral interface (SPI) register map, external SYNC input, and repeatable multichip alignment in both integer and fractional mode.

Resolution				8	Bits	

<sup>1</sup>  $0.9 \text{ V} < V_{\text{CP}} < V_{5V\_CP} - 0.9 \text{ V}$ .

<sup>2</sup> Valid for  $1.60 \text{ V} \leq V_{\text{TUNE}} \leq 2.85 \text{ V}$  with part calibrated after a power cycle or software power-on reset.

<sup>3</sup> Based on characterization.

<sup>4</sup> Temperature range is covered by autocalibration only. Manual calibration also provides full range provided an autocalibration has been performed to obtain VCO values.

<sup>5</sup>  $V_{\text{OD}}$  is the output differential voltage.

<sup>6</sup> These values are modeled in ADIsimPLL.

<sup>7</sup> Integrated ranged 1 kHz to  $f_{\text{OUT}}$ .

## ABSOLUTE MAXIMUM RATINGS

$T_A = 25^\circ\text{C}$ , unless otherwise noted.

**Table 3. Absolute Maximum Ratings**

Parameter	Rating
$V_{3.3V\_1}$ ( $V3\_LS$ , $V3\_LDO$ , $V3\_REF$ , $V3\_PFD$ , and $V3\_NDIV$ ) to GND	-0.3 V to +3.6 V
$V_{3.3V\_2}$ ( $V3\_VCO$ , $V3\_OUTDIV$ , $V3\_RFOUT1$ , and $V3\_FOUT2$ ) to GND	-0.3 V to +3.6 V
$V_{V5\_CAL}$ , $V_{V5\_VCO}$ , and $V_{V5\_CP}$ to GND	-0.3 V to +5.5 V
Voltage on CP Pin	-0.3 V to $V_{V5\_CP} + 0.3$ V
Voltage on All Other Pins	-0.3 V to $V_{3.3V\_1} + 0.3$ V
Digital Outputs (MUXOUT, LKDET, SDO, and SDIO)	5 mA
RFOUT1P/RFOUT1N and RFOUT2P/RFOUT2N	Maximum (GND - 0.3 V, $V_{3.3V\_2} - 1.2$ V) to $V_{3.3V\_2} + 0.3$ V
REFP and REFN	-0.65 V to $V_{3.3V\_1} + 0.65$ V
Voltage on all Other Pins	-0.3 V to $V_{3.3V\_1} + 0.3$ V
REFP to REFN and SYNCN to SYNCN	$\pm 1.35$ V
Temperature	
Operating Junction Range	-40°C to +125°C
Storage Range	-55°C to +150°C
Maximum Junction	150°C
Reflow Soldering	
Peak Temperature	260°C
Time at Peak Temperature	30 sec

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

## THERMAL RESISTANCE

Thermal performance is directly linked to printed circuit board (PCB) design and operating environment. Careful attention to PCB thermal design is required.

$\theta_{JA}$  is specified for the worst-case conditions, that is, a device soldered in a circuit board for surface-mount packages.  $\theta_{JC-TOP}$  and  $\theta_{JC-BOTTOM}$  are the junction-to-case thermal resistance top and bottom.

**Table 4. Thermal Resistance**

Package Type <sup>1</sup>	$\theta_{JA}$	$\theta_{JC-TOP}$	$\theta_{JC-BOTTOM}$	Unit
CC-48-10	25.23	16.11	5.10	°C/W

<sup>1</sup> Test Condition 1: thermal impedance simulated values are based on use of a 4-layer PCB with the thermal impedance paddle soldered to a ground plane.

## TRANSISTOR COUNT

The transistor count for the ADF4383 is 4700 (bipolar) and 385,400 (CMOS).

## ELECTROSTATIC DISCHARGE (ESD) RATINGS

The following ESD information is provided for handling of ESD-sensitive devices in an ESD protected area only.

Human body model (HBM) per ANSI/ESDA/JEDDEC JS-001.

Charged device model (CDM) per ANSI/ESDA/JEDEC JS-002.

## ESD Ratings for ADF4383

**Table 5. ADF4383, 48-Terminal LGA**

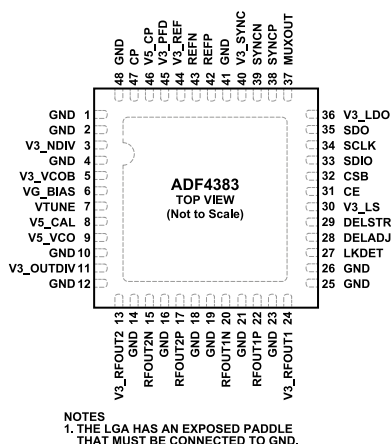

ESD Model	Withstand Threshold (V)	Class
HBM	4000	3A
CDM	1000	C3

## ESD CAUTION

**ESD (electrostatic discharge) sensitive device.** Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

**Figure 6. Pin Configuration**

**Table 6. Pin Function Descriptions**

Pin No.	Mnemonic	Description
1, 2, 4, 10, 12, 14, 16, 18, 19, 21, 23, 25, 26, 41, 48	GND	Negative Power Supply (Ground). Tie the GND pins directly to the ground pad.
3	V3_NDIV	3.15 V to 3.45 V Positive Power Supply Pin for the PLL Feedback Divider Circuitry. Short the V3_NDIV pin to the other pins in the 3.3 V Power Supply Group 1.
5	V3_VCOB	3.15 V to 3.45 V Positive Power Supply Pin for the Bias Circuitry and Digital Logic Control Portion of the VCO. Short the V3_VCOB pin to the other pins in the 3.3 V Power Supply Group 2.
6	VG_BIAS	Bias Decoupling Pin. Connect uninstalled 0402, 0.1 $\mu$ F capacitor footprint to GND.
7	VTUNE	VCO Tuning Input. This frequency control pin is normally connected to the external loop filter.
8	V5_CAL	4.75 V to 5.25 V Positive Power Supply Pin for VCO Calibration Circuitry. The V5_CAL pin can be shorted to the V5_VCO supply plane.
9	V5_VCO	4.75 V to 5.25 V Positive Power Supply Pin for the VCO Circuitry.
11	V3_OUTDIV	3.15 V to 3.45 V Positive Power Supply Pin for the Output Divider Circuitry. Short the V3_OUTDIV pin to the other pins in the 3.3 V Power Supply Group 2.
13	V3_RFOUT2	3.15 V to 3.45 V Positive Power Supply Pin for the RFOUT 2 Buffer Circuitry. Short the V3_RFOUT2 pin to the other pins in the 3.3 V Power Supply Group 2.
15, 17	RFOUT2N, RFOUT2P	RF Output 2 Output Signal. The VCO output divider is buffered and presented differentially on the RFOUT2N and RFOUT2P pins. The outputs have a 50 $\Omega$ (typical) output resistance per side (100 $\Omega$ differential). The far end of the transmission line is typically terminated with 100 $\Omega$ connected across the outputs. The output amplitude is programmable via the serial port.
20, 22	RFOUT1N, RFOUT1P	RF Output 1 Output Signal. The VCO output divider is buffered and presented differentially on the RFOUT1N and RFOUT1P pins. The outputs have 50 $\Omega$ (typical) output resistance per side (100 $\Omega$ differential). The far end of the transmission line is typically terminated with 100 $\Omega$ connected across the outputs. The output amplitude is programmable via the serial port.
24	V3_RFOUT1	3.15 V to 3.45 V Positive Power Supply Pin for the RFOUT 1 Buffer Circuitry. Short the V3_RFOUT1 pin to the other pins in the 3.3 V Power Supply Group 2.
27	LKDET	PLL Lock Detect. This output presents the lock status of the PLL. The PLL is locked when LKDET is a logic high.
28	DELADJ	Delay Adjust Input Signal. Logic 0 ensures that the delay of the RF output signal is reduced after DELSTR is asserted. Logic 1 ensures that the delay of the RF output signal is increased after DELSTR is asserted.
29	DELSTR	Delay Strobe Input Signal. A rising edge on this signal indicates that an adjustment is needed. The adjustment is then made on the falling edge.
30	V3_LS	3.15 V to 3.45 V Positive Power Supply Pin for the Internal Level Shift Circuitry. Short the V3_LS pin to the other pins in the 3.3 V Power Supply Group 1.
31	CE	Chip Enable. 3.3 V CMOS input. Does not support 1.8 V CMOS levels. This CMOS input enables the device when driven high. A logic low disables the device, putting the device in a full power-down state causing the register to reset. Conversely, the PD_ALL bit powers down the device, but does not reset the registers.

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

Table 6. Pin Function Descriptions (Continued)

Pin No.	Mnemonic	Description
32	CSB	Serial Port Chip Select. This CMOS input initiates a serial port communication burst when driven low, ending the burst when driven back high.
33	SDIO	Serial Data Input/Output. CMOS input and output. When configured as an input, the serial port uses this CMOS input for data. In 3-wire readback mode (default mode), the SDIO pin outputs data from the serial port during a read communication burst.
34	SCLK	Serial Port Clock. This CMOS input clocks serial port input data on its rising edge.
35	SDO	Optional Serial Data Output. In 3-wire mode (default mode), this three-state CMOS pin remains in a high impedance state. In 4-wire readback mode, the SDO pin presents data from the serial port during a read communication burst. When the CSB is de-asserted, SDO returns to a high impedance. Optionally, attach a resistor of >200 k $\Omega$ to prevent a floating output.
36	V3_LDO	3.15 V to 3.45 V Positive Power Supply Pin for the Internal Low Dropout (LDO) Regulator Circuitry. Short the V3_LDO pin to the other pins in the 3.3 V Power Supply Group 1.
37	MUXOUT	Internal Device Multiplexor Output. This output pin can be connected to multiple internal nodes for factory test and debug purposes.
38, 39	SYNCP, SYNCN	Synchronization Input Signals. Both RF output signals are synchronized to an input signal at these pins. SYNCP and SYNCN are used for multichip phase synchronization. This differential input can accept both high and low common-mode input signals (based on the SPI bit setting).
40	V3_SYNC	3.15 V to 3.45 V Positive Power Supply. Short the V3_SYNC pin to the other pins in the 3.3 V Power Supply Group 1.
42, 43	REFP, REFN	Reference Input Signals. These differential inputs are buffered with a low noise amplifier (LNA) ideally suited for high slew rates (default mode). For low slew rate reference input signals, an alternate LNA can be selected via the serial port. Reference inputs are self biased and must be AC-coupled with 1 $\mu$ F capacitors. Reference inputs accept differential or single-ended inputs. See the <a href="#">Reference Input Network</a> section for more details.
44	V3_REF	3.15 V to 3.45 V Positive Power Supply Pin for the PLL Reference Circuitry. Short the V3_REF pin to the other pins in the 3.3 V Power Supply Group 1.
45	V3_PFD	3.15 V to 3.45 V Positive Power Supply Pin for PFD Circuitry. Short the V3_PFD pin to the other pins in the 3.3 V Power Supply Group 1.
46	V5_CP	4.75 V to 5.25 V Positive Power Supply Pin for Charge Pump Circuitry. Isolate the V5_CP pin from the V5_VCO supply plane.
47	CP	Charge Pump Output. This bidirectional current output is normally connected to the external loop filter.
Exposed Pad	GND	Negative Power Supply (Ground). The package exposed pad must be soldered directly to the PCB land. The PCB land pattern must have multiple thermal vias to the ground plane for both low ground inductance and low thermal resistance.

THEORY OF OPERATION

INTRODUCTION

A PLL is a complex feedback system that can conceptually be considered a frequency multiplier. The system multiplies the frequency input at REFP/REFN and outputs a higher frequency at RFOUTxP/RFOUTxN. The PFD, charge pump, output divider, feedback divid-

er, VCO, and external loop filter form a feedback loop to accurately control the output frequency (see Figure 45). When operating in integer mode, the reference divider or reference doubler sets the frequency resolution. When operating in fractional mode, the fractional-N divider sets the frequency resolution.

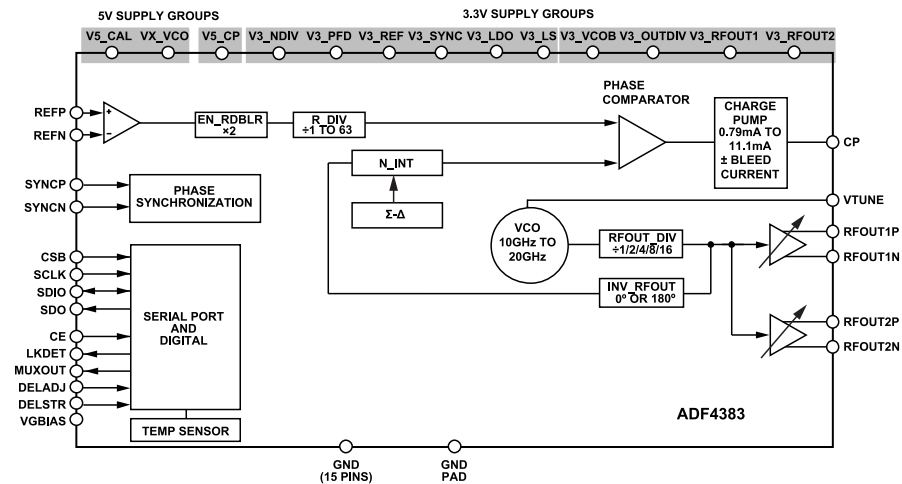

Figure 45. PLL Loop Diagram

## THEORY OF OPERATION

### OUTPUT FREQUENCY

When the loop is locked, the  $f_{VCO}$  (in Hz) produced at the output of the VCO is determined by  $f_{REF}$  and the O, R, and N values given by the following equation.

$$f_{VCO} = f_{REF} \times \frac{D \times N \times O}{R} \quad (1)$$

where:

$f_{REF}$  is the reference frequency.

D is the reference doubler.

R is the reference divider.

O is the output divider.

$f_{PFD}$  is given by the following:

$$f_{PFD} = \frac{f_{REF} \times D}{R} \quad (2)$$

and  $f_{VCO}$  can be alternatively expressed as follows:

$$f_{VCO} = f_{PFD} \times N \times O \quad (3)$$

The output frequency,  $f_{RFOUT}$ , produced at the output of the output divider is given by the following:

$$f_{RFOUT} = \frac{f_{VCO}}{O} \quad (4)$$

N is the feedback divider and is given by the following:

$$N = N_{INT} + \frac{FRAC1WORD + \frac{FRAC2WORD}{MOD2WORD}}{MOD1WORD} \quad (5)$$

## CIRCUIT DESCRIPTION

### Reference Input Buffer

The reference frequency of the PLL is applied differentially on the REFP and REFN pins. These high impedance inputs are self biased and must be AC-coupled with 1  $\mu$ F capacitors (see Figure 46 for a simplified schematic). Alternatively, the inputs can be used single ended by applying the reference frequency at REFP and bypassing REFN to GND with a 1  $\mu$ F capacitor.

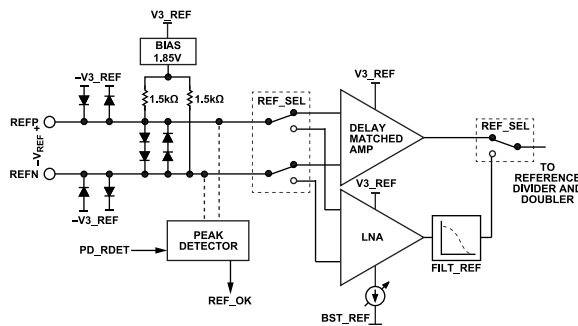

Figure 46. Reference Input Stage

A high quality signal must be applied to the REFP and REFN inputs as these inputs provide the frequency reference to the entire PLL. To achieve the in-band phase noise performance of the ADF4383, apply a continuous wave signal or a square wave with a slew rate of at least 1000 V/ $\mu$ s. See the [Reference Source Considerations](#) section for more information on reference input signal requirements and interfacing.

The REF\_SEL bit (Register 0x030, Bit 5) can be set to either a CML reference input or sine wave or slow slew-rate reference input. When REF\_SEL is set to 0, the delay matched amplifier (DMA) buffer is selected. The DMA is optimized for high slew rate signals, such as square waves or higher frequency and higher amplitude sine waves. The DMA has a controlled propagation delay from the reference input to clock output, which eases time zero and over temperature multichip clock alignment.

When the REF\_SEL bit is set to 1, the LNA is selected. The LNA is optimized for low slew rate signals, such as lower frequency or lower amplitude sine waves.

The REF\_SEL bit must be set correctly to optimize the in-band phase noise performance and propagation delay,  $t_{PD}$ . See [Table 7](#) for recommended settings.

Table 7. REF\_SEL Programming

REF_SEL	Sine Wave Slew Rate (V/ $\mu$ s)	Square Wave	Optimized $t_{PD}$
0	$\geq 1000$	Preferred	Yes
1	$< 1000$	Not applicable	Not applicable

To calculate the slew rate of a sine wave, use the following equation:

$$\text{Slew Rate} = 2 \times \pi \times f \times V \quad (6)$$

where:

$f$  is the sine wave frequency.

$V$  is the sine wave amplitude (in V peak)

The FILT\_REF bit (Register 0x02F, Bit 6) controls the reference input LPF of the LNA and must be set only for sine wave signals less than 20 MHz to limit the wideband noise of the reference. The FILT\_REF bit must be set correctly to reach the normalized in-band phase noise floor ( $L_{NORM}$ ). Square wave inputs have FILT\_REF set to 0. [Table 8](#) shows the recommended settings.

Table 8. FILT\_REF Programming

FILT_REF	Sine Wave $f_{REF}$ (MHz)	Square Wave $f_{REF}$
0	$\geq 20$	All $f_{REF}$
1	$< 20$	Not applicable

The BST\_REF bit (Register 0x02F, Bit 7) must be set based upon the input signal level to prevent the LNA reference input buffer from saturating. The BST\_REF programming is the same whether the input is a sine wave or a square wave. See [Table 9](#) for recommended settings.

## THEORY OF OPERATION

Table 9. BST\_REF Programming

BST_REF	Sine Wave $f_{REF}$ (Vref)
0	$\geq 1.4$ V p-p
1	$< 1.4$ V p-p

### Reference Peak Detector

A reference input peak detection circuit is provided on the REFP and REFN inputs to detect the presence of a reference signal and provides the REF\_OK status flag available through Bit 3, Register 0x058. The circuit has hysteresis to prevent the REF\_OK flag from chattering at the detection threshold.

The peak detector approximates an RMS detector; therefore, sine and square wave inputs give different detection thresholds by a factor of  $4/\pi$ . See Table 10 for REF\_OK detection values.

Table 10. REF\_OK Status Output vs. Reference Input

REF_OK	Sine Wave $f_{REF}$ (mV p-p)	Square Wave $f_{REF}$ (mV p-p)
1	$\geq 200$	$\geq 155$
0	$< 180$	$< 140$

### Reference Divider (R) and Doubler (D)

When the EN\_RDBLR bit (Register 0x020, Bit 6) is set to 1, a frequency multiplier is used to double the frequency driven to the reference divider. A 6-bit divider, R\_DIV (Register 0x020, Bits[5:0]), in series with reference doubler is used to reduce the frequency seen at the PFD. Its divide ratio, R, can be set to any integer from 1 to 63, inclusive. Use the R\_DIV bits to directly program the R-divide ratio. See the [Output Frequency](#) section for the relationship between R and D and the  $f_{REF}$ ,  $f_{PFD}$ ,  $f_{VCO}$ , and  $f_{RFOUT}$  frequencies.

When using the reference doubler, refer to Table 11 for the required bit field settings that must be used for optimal jitter performance. Target reference frequency refers to the reference frequency after the doubler stage.

Table 11. Reference Doubler Settings

Target Reference Frequency	RDBLR_DEL_SEL	RDBLR_DC	INV_RDBLR
$< 1$ GHz	1	0	0
$\leq 1.6$ GHz	3	7	1
1.6 GHz to 4.5 GHz	1	0	1

### Phase/Frequency Detector (PFD)

The PFD, in conjunction with the charge pump, produces source and sink current pulses proportional to the phase difference between the outputs of the reference divider or reference doubler and feedback divider. These source and sink pulses are required to phase lock the loop, forcing a phase alignment at the inputs of the PFD. See Figure 47 for a simplified schematic of the PFD.

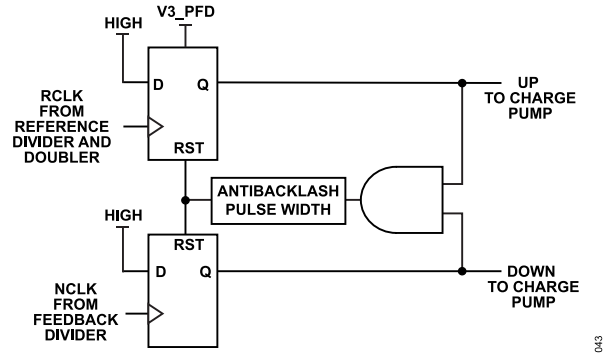

Figure 47. Simplified PFD Schematic

### Charge Pump

The charge pump, controlled by the PFD, forces sink (down) or source (up) current pulses onto the CP pin, which must be connected to an appropriate loop filter. See Figure 48 for a simplified schematic of the charge pump.

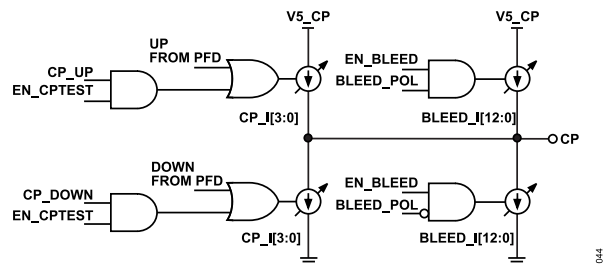

Figure 48. Simplified Charge Pump Schematic

The output current magnitude  $I_{CP}$  can be set from 0.79 mA to 11.1 mA using the CP\_I bits (Register 0x001F, Bits[3:0]). A larger  $I_{CP}$  can result in lower in-band noise due to the lower impedance of the loop filter components, while a smaller  $I_{CP}$  can result in better spurious performance. See Table 12 for charge pump programming values.

Table 12. CP Programming

## Charge Pump Test Mode

When the EN\_CPTTEST bit (Register 0x02E, Bit 2) is set to 1, the CP\_UP and CP\_DOWN bits (Bit 1 and Bit 0, respectively) in the same register can be programmed to force a constant I<sub>CP</sub> source or sink current, respectively, on the CP pin. The EN\_CPTTEST or CP\_UP and CP\_DOWN bits must be set to 0 to allow the loop to lock. These bits can be used as an aid to debug PLL-related issues during the hardware and software development phase of a project. For normal operation, set EN\_CPTTEST, CP\_UP, and CP\_DOWN to 0.

Table 13. Charge Pump Test Mode

EN_CPTTEST	CP_UP	CP_DOWN	CP Pin State	Debug Test
1	0	0	High-Z	VCO open loop
1	1	0	~V <sub>V5_CP</sub>	Charge pump output voltage verification
1	0	1	~GND	Charge pump output voltage verification
0	0	0	Normal operation	Not applicable

## Charge Pump Bleed Current Optimization

A small programmable constant charge pump current, known as bleed current, can be used to optimize the phase noise and fractional spurious signals in fractional mode, which also changes the propagation delay (t<sub>BLEED</sub>) from the REFP and REFN input pins to the RFOUTP and RFOUTN output pins. In fractional mode, after setting the bleed current for best performance, the output can be shifted by using the phase word which is effectively used in the Σ-Δ modulator (SDM). In integer mode, bleed current can be used to shift the output in both directions.

To enable the bleed current, set the EN\_BLEED bit to 1. When the BLEED\_POL bit is set to 1, a small constant source current is forced onto the CP pin. When the BLEED\_POL bit is set to 0, a small constant sink current is forced onto the CP pin.

The 13-bit bit field BLEED\_I (Register 0x01D, Bits[7:0] and Register 0x01E, Bits[4:0]) is used to select the bleed current. This bit field consists of both a coarse bleed and a fine bleed value. The 4 MSBs are used to calculate the coarse bleed current, and the 9 LSBs are used to calculate the fine bleed current as shown in the following equations.

$$I_{COARSE\ BLEED} = COARSE\_BLEED \times 202 \mu A \quad (7)$$

$$I_{FINE\ BLEED} = FINE\_BLEED \times 567 \text{ nA} \quad (8)$$

$$I_{TOTAL\ BLEED} = I_{COARSE\ BLEED} + I_{FINE\ BLEED} \quad (9)$$

The propagation delay of the output frequency corresponds to the I<sub>TOTAL BLEED</sub> as follows:

$$t_{BLEED} = \frac{I_{TOTAL\ BLEED}}{I_{CP}} \times t_{PFD} \quad (10)$$

where:

I<sub>COARSE BLEED</sub> is the coarse bleed current.

COARSE\_BLEED represents the 4 upper MSBs of the BLEED\_I bit field.

I<sub>FINE BLEED</sub> is the fine bleed current.

FINE\_BLEED represents the lower 9 LSBs of the BLEED\_I bit field.

I<sub>CP</sub> is the charge pump current value selected.

# THEORY OF OPERATION

## Bleed Current Modes

The ADF4383 spurious performance can be optimized by programming  $t_{BLEED}$  setting based on the frequency of operation. The recommended  $t_{BLEED}$  for the RFOUT frequency of operation for each of the SDM modes are shown in Table 14.

To calculate the required BLEED\_I setting required for a specific  $t_{BLEED}$  with the bleed current refer to Charge Pump Bleed Current Optimization section. Figure 49 provides a quick reference for delay step sizes for different charge pump settings and  $f_{PFD}$  frequencies.

Figure 49. Bleed Current Delay Step Size

Table 14. Bleed Setting vs. Frequency for Each SDM Mode

RFOUT	$t_{BLEED}$ (ps)		
	SDM Mode 0	SDM Mode 4	SDM Mode 5
$RFOUT \geq 10$ GHz	300	510	720
$3.996 \text{ GHz} \leq RFOUT < 10$ GHz	625	$625 + (2/RFOUT)$	$900 + (1.7/RFOUT)$
$1.8 \text{ GHz} \leq RFOUT < 3.996$ GHz	1000	1350	$1400 + (4/RFOUT)$
$RFOUT < 1.8$ GHz	3600	3600	$3600 + (4/RFOUT)$

## THEORY OF OPERATION

## Lock Detector

The lock detector uses internal signals from the PFD to measure the phase difference between the output signal of the reference divider and doubler (RCLK) and the output signal of the feedback divider (NCLK) in Figure 47. This detector is enabled by setting both the EN\_LOL and EN\_LDWIN bits (Register 0x02D, Bit 5 and Bit 4, respectively) to 1 and presents the lock detector output on the LKDET pin (Pin 27) and the LOCKED bit (Register 0x58, Bit 0). The lock detector output can also be presented on the MUXOUT pin (Pin 37 by programming the MUXOUT bits in Register 0x2E, Bits[7:4], to b0001).

The PFD RCLK and NCLK phase difference must be less than the phase difference lock window time,  $t_{LDWIN}$ , for a set number of PFD cycles before the lock detector output indicates the PLL has locked. The desired number of PFD cycles vary depending on whether the lock detect accuracy or speed is prioritized. Five loop filter time constants can be used as an initial estimate of the desired number of PFD cycles, as shown in the following equation:

$$PFD\ Cycles = \frac{5}{2 \times \pi \times LFBW} \times f_{PFD} \quad (11)$$

where LFBW means loop filter bandwidth.

Note that LD\_COUNT bits (Register 0x02C, Bits[4:0]) are used to select the desired number of PFD cycles. Use Table 15 to select the LD\_COUNT value for the desired number of PFD cycles.

Table 15. LD\_COUNT Programming

LD_COUNT[4:0]	PFD Cycles

Figure 50. Lock Detector Timing, Bleed Current Disabled

Table 16. Lock Detector Timing, Bleed Current Disabled

Region	Absolute Phase Difference at PFD	Lock Detector State
1	$>t_{LDWIN}$	Low
2	$<t_{LDWIN}$	Low, counts PFD cycles
3	$\sim 0$	Low, counts PFD cycles
4	$\sim 0$	High, greater than or equal to the desired PFD cycle count
5	$<t_{LDWIN}$	High
6	$>t_{LDWIN}$	Low (immediately)

When the charge pump bleed current is enabled, a phase offset is applied to the PFD inputs. This phase offset,  $t_{IDEL}$ , is proportional to the amount of bleed current. Region 3 and Region 4 in Figure 50 and Figure 51 highlight the PFD phase difference the PLL settles to when the charge pump bleed current is disabled or enabled, respectively.

Figure 51. Lock Detector Timing, Bleed Current Enabled

For proper operation of the lock detector, the absolute value of  $t_{IDEL}$  must be less than  $t_{LDWIN}$ . The user sets the phase difference lock

# THEORY OF OPERATION

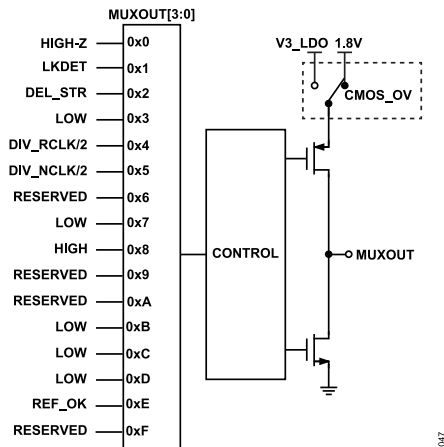

window time ( $t_{LDWIN}$ ) for a valid lock condition with the LDWIN\_PW bit field (Register 0x02C, Bits[7:5]).

111	Fractional PLL, 40 MHz maximum PFD, RFOUT $\geq 800$ MHz

# MUXOUT

The state of the MUXOUT pin is determined by the MUXOUT bits (Register 0x02E, Bits[7:4]), which allow the user access to various internal nodes. The MUXOUT pin and MUXOUT bits are commonly used as an additional lock status output or to debug PLL-related issues during the hardware and software development phase of a project. The CMOS\_OV bit (Register 0x03D, Bit 5) determines if the logic high level for the MUXOUT pin, LKDET pin, SDO pin, and SDIO pin is 3.3 V or 1.8 V.

**Figure 52. MUXOUT**

# Temperature Sensor

The temperature sensor is composed of an 8-bit ADC, which measures the proportional to absolute temperature (PTAT) voltage with respect to the reference voltage (VREF) of a bandgap. The purpose of the temperature sensor is to measure changes in the die temperature and not the absolute junction temperature. The maximum ADC clock frequency is 400 kHz. The ADC clock is generated from the RCLK.

**Figure 53. Temperature Sensor**

Before an ADC measurement can occur, program the registers of the ADF4383 as shown in Table 18.

**Table 18. ADC Register Setup**

Bit Fields	Value
EN_DRCLK, EN_DNCLK, EN_ADC_CNV	1
ADC_ST_CNV, EN_ADC, EN_ADC_CLK	1
PD_ADC	0

After the bits in Table 18 are programmed, start an ADC conversion with a register write to Register 0x054 setting ADC\_ST\_CNV = 1. An ADC conversion requires 17 clock cycles to complete. In Register 0x058, Bit 2, the ADC\_BUSY bit monitors the conversion status. During a conversion, ADC\_BUSY is set to 1, and when the conversion is complete, ADC\_BUSY is set to 0. Measurements are recorded in the CHIP\_TEMP bit field, Bits[8:0], in Register 0x05B and Register 0x05C. The value read back represents the junction temperature in degrees celsius. The MSB (Bit 8) indicates positive or negative temperature i.e. when Bit 8 = 1, the temperature read back is negative.

# Double Buffering

Double buffering refers to a main and subordinate configuration for the bit fields shown in Table 19.

Only the subordinate bit fields control the actual state of the ADF4383. When double buffering is enabled for a bit field, the serial interface only writes to the main bit field. The subordinate bit field retains its previous value until a register write is sent to Register 0x010. After writing to Register 0x010, all the main bit fields are automatically loaded to their respective subordinate bit fields. Writing to Register 0x010 also starts the autocalibration of the VCO (see the Standard Power-Up and Initialization Sequence, Automatic VCO Calibration section), which allows the user to update several bit fields that change the output frequency of the ADF4383 and starts a new VCO calibration on the same register write. When double buffering is disabled, the SPI writes directly to the subordinate bit field.

**Table 19. Double Buffer Enabled Bit Fields**

Double Buffer Enabled Bits	Double Buffered Bit Fields
Not Applicable, Always Enabled	N_INT, R_DIV, EN_RDBLR, CP_I
RFOUTODIV_DB	RFOUT_DIV
DCLK_DIV_DB	DCLK_DIV1

THEORY OF OPERATION

Table 19. Double Buffer Enabled Bit Fields (Continued)

Double Buffer Enabled Bits	Double Buffered Bit Fields
DEL_CTRL_DB	INV_RFKOUT, BLEED_I, BLEED_POL

Serial Port

The SPI-compatible serial port provides control and monitoring functionality. The CMOS\_OV bit (Register 0x03D, Bit 5) determines if the logic high level for the SDO and SDIO SPI output pins is 3.3 V or 1.8 V. The CMOS\_OV bit also sets the output level for the MUXOUT and LKDET pins.

The serial port can be programmed to support several different configurations in Register 0x000 and Register 0x001.

The SDO\_ACTIVE bit (Register 0x000, Bit 3) determines if the serial port is configured as a 3-wire or 4-wire serial interface (see the timing diagrams in Figure 2, Figure 3 and Figure 4).

Figure 54. Serial Interface, MSB First (LSB\_FIRST = 0)

Figure 55. Serial Interface, LSB First (LSB\_FIRST = 1)

The SPI register map can be programmed with single instructions, as shown in Figure 54 and Figure 55, or in streaming mode. Streaming mode allows for efficient data transfer read or write cycles to multiple registers. Streaming mode allows the user to program a bit stream composed of one register address in the instruction header and data for that register address, which is then followed by data in subsequent register addresses.

VCO

The VCO core consists of two separate VCOs both of which uses 512 overlapping bands, which allows the device to cover a wide frequency range without large VCO tuning sensitivity ( $K_{VCO}$ ). The

output frequency can be further extended by utilizing the output divider.

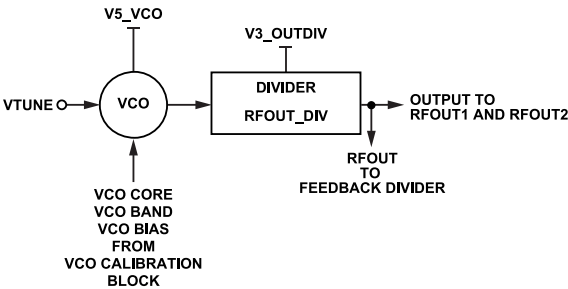

Figure 56. VCO and Clock Output Divider

The correct VCO core, band, and bias are chosen automatically by performing a VCO calibration. After a VCO calibration is performed for a specific frequency, the VCO core, band, and bias values can be recorded for that particular device. These values can be programmed manually later when the same device and frequency are used, thereby avoiding the VCO calibration time.

VCO Calibration

A VCO calibration is required to select the correct VCO core, band, and bias settings for a specific VCO frequency. This procedure assumes that the device is powered up, the desired reference frequency is present on the REFP and REFN pins, and all other registers are programmed correctly. Figure 57 and Figure 58 are provided as visual aids for this procedure.

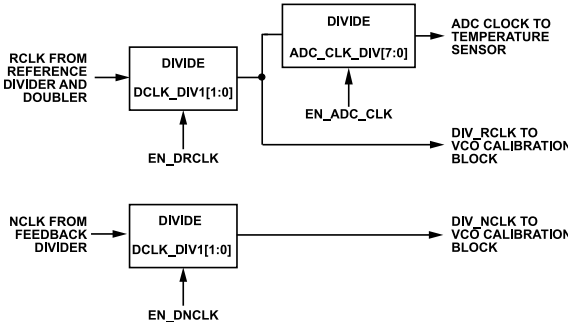

Figure 57. VCO Calibration Dividers

## THEORY OF OPERATION

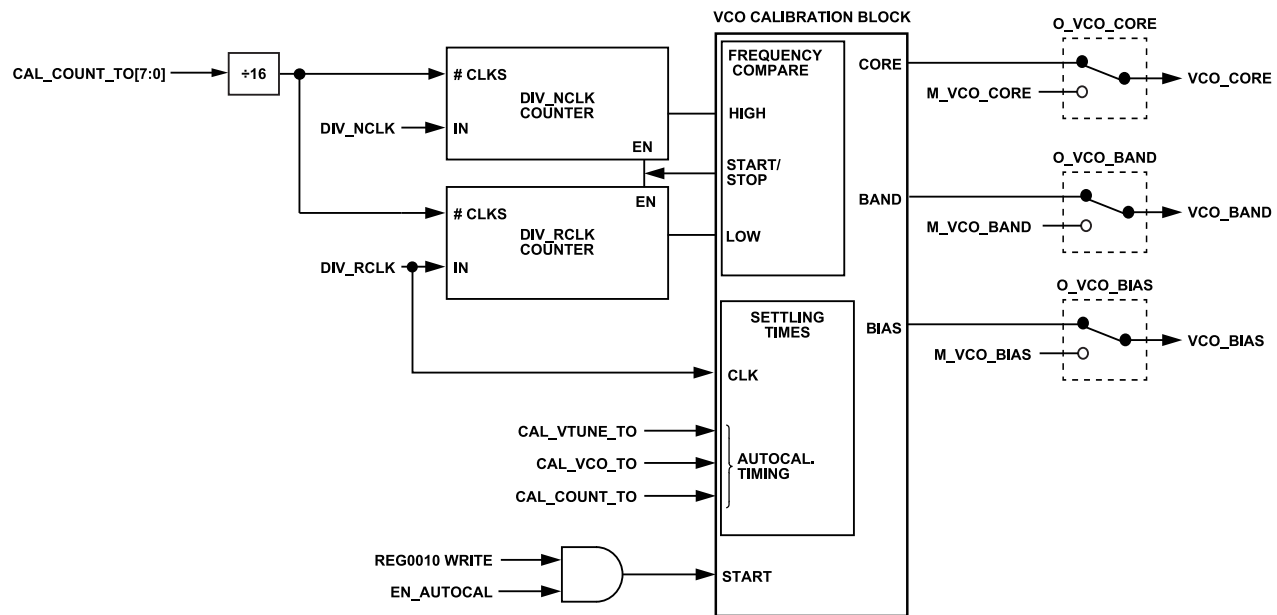

Figure 58. VCO Calibration Block

The following calibration timeout bit fields must be programmed for autocalibration:

- **CAL\_VTUNE\_TO**: At the beginning of the calibration, VTUNE is precharged to a nominal voltage, which is dependent on the temperature of operation. CAL\_VTUNE\_TO sets the precharge time as follows:

$$CAL\_VTUNE\_TO = \text{Ceiling} \left( \frac{CAL\_VTUNE\_TO \text{ Time} \times f_{PFD}}{2^{DCLK\_DIV1}} \right) \quad (12)$$

The largest value capacitor in the loop filter directly affects the time taken to precharge to VTUNE. Refer to the [Calibration Time Performance Consideration](#) section to calculate the CAL\_VTUNE\_TO time required. This time is used as the Target VTUNE Calibration Timeout.

- **CAL\_COUNT\_TO**: This is used to calculate the target band decision timeout. During autocalibration, there are nine band decisions to be made to select the final band of operation for the selected frequency. CAL\_COUNT\_TO is used to program the time taken for each band decision. This time affects the calibration accuracy. See [Table 21](#) for the recommended CAL\_COUNT\_TO time. Use the following equation to set the decision time of each band:

$$CAL\_COUNT\_TO = \text{Ceiling} \left( \frac{CAL\_COUNT\_TO \text{ Time} \times f_{PFD}}{2^{DCLK\_DIV1} \times 16} \right) \quad (13)$$

- **CAL\_VCO\_TO**: This bit field is used to set the target VCO frequency settling timeout after each band decision. As per [Table 21](#) the recommended CAL\_VCO\_TO time is 1μs. To set this time, use the following equation:

$$CAL\_VCO\_TO = \text{Ceiling}$$

$$\left( \frac{CAL\_VCO\_TO \text{ Time} \times f_{PFD}}{2^{DCLK\_DIV1}} \right) \quad (14)$$

To perform a VCO calibration, set up the following several registers as outlined in the following procedure:

1. Set DCLK\_DIV1 and DCLK\_MODE to the values listed in [Table 20](#) and record  $f_{DIV\_RCLK}$  for later use.
2. Calculate and set the minimum required values for CAL\_VTUNE\_TO, CAL\_VCO\_TO, and CAL\_COUNT\_TO as per their corresponding formulas previously described in this section.
3. Set the N\_INT, RFOUT\_DIV, and R\_DIV bits and the EN\_RDBLR bit by programming Register 0x010 last. Any writes to Register 0x010 start the VCO autocalibration.
4. Monitor the ADC\_BUSY bit and FSM\_BUSY bit (Register 0x058, Bit 2 and Bit 3, respectively). The calibration is finished when ADC\_BUSY transitions from high to low, followed with FSM\_BUSY transitioning from high to low.
5. After the VCO calibration is complete, disable the calibration clocks to limit unwanted spurious content by setting EN\_DRCLK = EN\_DNCLK = 0.

Table 20. DCLK\_DIV1 and DCLK\_MODE Setup

$f_{PFD}$ (MHz)	DCLK_DIV1	DCLK_MODE	$f_{DIV\_RCLK}$ (MHz)
≤11	0	0	$f_{PFD}$
>11 and ≤160	0	1	$f_{PFD}/2$
>160 and ≤320	1	1	$f_{PFD}/4$
>320	2	1	$f_{PFD}/8$

## THEORY OF OPERATION

### Total Autocalibration Time

Use each of the calibration timeout values to calculate the total autocalibration time as follows:

$$\text{Total Autocalibration Time} = \text{CAL\_VTUNE\_TO Time} + \left( \frac{2}{f_{DIV\_RCLK}} \right) + (10 \times \text{VCO Band Decision Time}) + \text{VCAL Time} \quad (15)$$

where:

$$\text{VCO Band Decision Time} = \text{CAL\_VCO\_TO Time} + \text{CAL\_COUNT\_TO Time} + \left( \frac{5}{f_{DIV\_RCLK}} \right) \quad (16)$$

$$f_{DIV\_RCLK} = \frac{f_{PFD}}{2^{DCLK\_DIV1} + DCLK\_MODE} \quad (17)$$

$$\text{VCAL Time} = \frac{2}{f_{DIV\_RCLK}} \quad (18)$$

### Calibration Time Performance Consideration

When programming the VCO calibration time as per the [VCO Calibration](#) section, the jitter performance can be affected by the overall calibration time. For applications where taking a longer time for calibration is not an issue, for example, fixed frequency applications, it is recommended to program an autocalibration time of 250  $\mu\text{s}$  to optimize jitter and phase noise performance. For other applications requiring faster autocalibration times and reduced overall lock times, an autocalibration time of 100  $\mu\text{s}$  can be used. However, this time may degrade jitter with temperature changes over the complete  $-40^{\circ}\text{C}$  to  $+105^{\circ}\text{C}$  operating range.

**Table 21. Recommended Calibration Times**

Autocalibration Time ( $\mu\text{s}$ )	CAL_VTUNE_TO Time	CAL_COUNT_TO Time ( $\mu\text{s}$ )	CAL_VCO_TO Time ( $\mu\text{s}$ )
100	Determined by the largest loop filter capacitor	8.5	1
250	Determined by the largest loop filter capacitor	23.5	1

### Core Bias Table

As part of the initialization process, the core bias table must be programmed with the predefined values provided in the [Register Map](#) section (see Register 0x100 through Register 0x111). These are specifically optimized VCO bias values for different frequency bands of operation. After performing a device initialization, the VCO bias registers are not reprogrammed until a subsequent power-on reset executes.

### RF Output Divider (O)

A 3-bit divider, RFOUT\_DIV (Register 11, Bits[7:5]), is used to divide the frequency seen at the output buffer and feedback divider. The divide ratio can be set to 1, 2, 4, 8, or 16. See [Table 22](#) for details on divider settings. RFOUT\_DIV is located inside the PLL. Therefore, any change to RFOUT\_DIV requires a change to the N\_INT bit fields (Register 0x010, Bits[7:0] and Register 0x011, Bits[3:0]) to maintain the same  $f_{PFD}$  and results in the PLL losing lock for a few loop time constants.

**Table 22. RFOUT\_DIV Programming**

RFOUT_DIV	Divisor	Output Frequency Range (GHz)
0	1	$10 \leq \text{RFOUT} \leq 20$
1	2	$5 \leq \text{RFOUT} < 10$
2	4	$2.5 \leq \text{RFOUT} < 5$
3	8	$1.25 \leq \text{RFOUT} < 2.5$
4	16	$0.625 \leq \text{RFOUT} < 1.25$

### Output Invert (INV\_RFOUT)

The output invert, INV\_RFOUT (Register 0x011, Bit 4), is used to shift the output signal  $180^{\circ}$ . INV\_RFOUT is located inside the PLL, and any change to INV\_RFOUT results in the PLL losing lock for a few loop time constants.

### Feedback Divider (N)

The feedback divider provides a division ratio in the PLL feedback path. The division ratio consists of the N\_INT (Register 0x011, Bits[3:0] and Register 0x010, Bits[7:0]), FRAC1WORD (Register 0x15, Bit 0; Register 0x14, Bits[23:16]; Register 0x013, Bits[15:8], and Register 0x012, Bits[7:0]), FRAC2WORD (Register 0x19, Bits[23:16]; Register 0x18, Bits[15:8]; and Register 0x17, Bits[7:0]), and MOD2WORD (Register 0x1C, Bits[23:16]; Register 0x1B, Bits[15:8]; and Register 0x1A, Bits[7:0]) bit field values that this divider comprises together with the fixed modulus MOD1WORD ( $2^{25}$ ). See the [Output Frequency](#) section for the relationship between N\_INT, FRAC1WORD, MOD1WORD, FRAC2WORD, MOD2WORD, RFOUT\_DIV, together with R and D, and the  $f_{REF}$ ,  $f_{PFD}$ ,  $f_{VCO}$  and  $f_{OUT}$  frequencies.

### Phase Adjust

One of the following two methods can be used to perform a phase adjustment of the RFOUT signals relative to their initial phase:

- Bleed current mode
- $\Sigma$ - $\Delta$  mode

To enable bleed current mode, set DEL\_MODE = 0. To enable  $\Sigma$ - $\Delta$  mode, set DEL\_MODE = 1.

## THEORY OF OPERATION

### Bleed Current Phase Adjustment

A small programmable constant charge pump current, known as a bleed current, can be applied to the charge pump to adjust the phase. Bleed current phase adjustment is used in integer mode. Bleed current can also be applied in fractional mode to optimize performance (see the [Charge Pump Bleed Current Optimization](#) section for more details). The LSB step size depends on the RFOUT frequency. PHASE\_ADJ\_POL determines the direction of the phase adjustment. When PHASE\_ADJ\_POL = 0, the phase value is decreased. When PHASE\_ADJ\_POL = 1, the phase value is increased.

Ensure the following bit fields are programmed accordingly to enable bleed current adjustment:

1. Set EN\_BLEED = 1.
2. Set EN\_PHASE\_RESYNC = 1.
3. Set DEL\_MODE = 0.
4. Use PHASE\_ADJUSTMENT to determine the amount by which the phase is adjusted as follows:

$$\text{PHASE\_ADJUSTMENT} = \left( \frac{\text{Phase in Degrees} \times 511}{250 \mu\text{A}} \right) \times I_{CP} \times \frac{f_{PFD}}{360 \times \text{RFOUT}} \quad (19)$$

The maximum adjustment time that can be achieved using the bleed current method is  $t_{\text{RFOUT}}$ .

The bleed current applied can be read back from DEL\_CNT.

### $\Sigma$ - $\Delta$ Modulator Phase Adjustment

The  $\Sigma$ - $\Delta$  modulator can be used to adjust the phase of the RFOUT signal by applying an offset value. The device must be used in fractional mode to adjust the  $\Sigma$ - $\Delta$  modulator, which is the case whether a fractional or integer frequency is used. Note that the in-band figure of merit degrades by 2 dB as compared with using integer mode. In addition, the maximum  $f_{\text{PFD}}$  is then 250 MHz in fractional mode, as compared to 625 MHz in integer mode.

An advantage of using fractional mode for adjusting the phase is that the range is infinite, which means that each time a phase adjust is performed, the phase increments by the value stored in the PHASE\_ADJUSTMENT bits (Register 0x033, Bits[7:0]) without any limit to the number of times this can be done.

Ensure that the following bit fields are programmed accordingly to enable  $\Sigma$ - $\Delta$  phase adjustment:

1. Set EN\_PHASE\_RESYNC = 1.
2. Set DEL\_MODE = 1.
3. Use PHASE\_ADJUSTMENT to determine the amount by which the phase is adjusted for the  $\Sigma$ - $\Delta$  modulator as follows:

$$\text{PHASE\_ADJUSTMENT} = \left( \frac{\text{Phase in Degrees}}{360} \right) \times 2^{12} \quad (20)$$

PHASE\_ADJ\_POL selects the direction of adjustment.

PHASE\_ADJ\_POL = 0 is positive and PHASE\_ADJ\_POL = 1 is negative. The PHASE\_ADJUSTMENT value currently applied can be read back from the CUM\_PHASE\_ADJ bits (Register 0x061, Bits[7:0]). The maximum value is 8192 decimal. If this value is exceeded, the value overflows and wraps around.

When the required phase offsets are known prior to initializing the device, the PHASE\_WORD bits can be used to program an initial phase offset using the same PHASE\_ADJUSTMENT formula in this section.

### Phase Adjust Pins

The ADF4383 has a 2-wire digital interface bus protocol that allows external control of the phase. This bus consists of DELSTR (Pin 29) and DELADJ (Pin 28). The signals are CMOS output signals with 1.8 V logic. This interface can be used in both bleed current and  $\Sigma$ - $\Delta$  mode phase adjustment. To enable the 2-wire interface, set EN\_AUTO\_ALIGN = 1.

DELSTR is an active high signal that is used to assert a phase adjustment. The amount by which the phase is adjusted is set in PHASE\_ADJUSTMENT. The phase is adjusted on the falling edge of the signal.

DELADJ is an active high signal that controls the direction of the adjustment. If the signal is set to 0 while DELSTR is high, the RFOUT signal phase adjusts to earlier in time relative to the initial phase. If the signal is set to 1 while DELSTR is high, the RF output signal advances in time relative to the initial phase.

Figure 59. DELSTR and DELADJ Timing Diagrams

### RF Output Buffer

The low noise, differential output buffer in [Figure 60](#) produces a differential output voltage. The output amplitude level and common-mode voltage is programmable with the RFOUT1\_OPWR (Register 0x029, Bits[3:0]) and RFOUT2\_OPWR (Register 0x029, Bits[7:4]) bits. Each output can be either AC- or DC-coupled and terminated with 100  $\Omega$  differentially. If a single-ended output is desired, each side of the output must be individually AC-coupled and terminated with 50  $\Omega$ . External inductors are required to achieve the highest output power. A 1.4 nH, 0402 sized, pull-up inductor is required to be connected to the RFOUTx 3.3 V supply (V3\_RFOUTx) from the RFOUTx pins. Additionally, a series 100 nF capacitor must be connected to the RFOUTx pins as shown in [Figure 61](#).

# THEORY OF OPERATION

Figure 60. Simplified RF Output Buffer Schematic

Figure 61. RFOUT Interface Schematic

## Mute RF Output

The RFOUTxP and RFOUTxN pins can be muted by using the MUTE\_RFOUTx bit fields (Register 0x40, Bits[5:3] and Bits[2:0], respectively).

Table 23. MUTE\_RFOUTx, Bit 0 through Bit 7, Controls

MUTE_RFOUTx, Bits	Function
0	Normal operation
1	Mute low and disable the emitter follower driver
2	Mute high and disable the emitter follower driver
3	Mute low and leave the emitter follower driver on
4	Mute low and disable the emitter follower driver during calibration
5	Mute low and keep the emitter follower running during calibration
6	Mute low and disable the emitter follower driver when LOCKED = 0
7	Mute low and keep the emitter follower running when LOCKED = 0

It is recommended to use options that keep the emitter follower on to minimize current fluctuations.

## APPLICATIONS INFORMATION

## POWER-UP AND INITIALIZATION SEQUENCE

The following steps describe the recommended power-up and initialization sequence of the ADF4383:

1. Apply specified voltages to the  $V_{5V}$ ,  $V_{3.3V\_1}$ , and  $V_{3.3V\_2}$  power supply groups. The ADF4383 is in full power-down mode at this point and SPI programming is not possible.
2. Set the CE pin to a logic high. It is acceptable to connect the CE pin to the  $V_{3\_LDO}$  pin via a pull-up resistor. Therefore, Step 1 and Step 2 are performed coincidentally.
3. After waiting  $\geq 200\ \mu\text{s}$  for all SPI register bits to settle to their power-on reset (POR) state, begin programming the SPI to configure the ADF4383 to a desired state. The following is the recommended SPI programming sequence:
  - a. Set the SDO\_ACTIVE and CMOS\_OV bits to a desired state for future readback operations.
  - b. Program all required register addresses. The ordering of programming does not matter except to ensure that Register 0x010 is the last register write. There are several required reserved register field settings provided in [Register Map](#) that are required for proper device operation.
4. The ADF4383 remains in power-down mode until the PD\_ALL bit is programmed to 0. After PD\_ALL is disabled, VTUNE is precharged in the loop filter to reduce VCO calibration time. The precharge time required before starting a VCO calibration depends on the largest value of capacitor in the loop filter. The wait time is:  $750 \times C_{MAX}$ , where  $C_{MAX}$  is the maximum value capacitor in the loop filter. The minimum precharge time is  $50\ \mu\text{s}$ .
5. A write to Register 0x010 starts a VCO autocalibration. At this point, the ADF4383 is fully operational and new frequencies can be programmed as often as desired. The following steps are information for the PD\_ALL bit and the CE pin.
6. Setting PD\_ALL to 1 power down the ADF4383, retaining the latest programmed SPI settings and full SPI programming capability.
7. If only the state of PD\_ALL was modified in Step 6, setting PD\_ALL to 0 returns the ADF4383 to the frequency programmed in Step 5. After a  $10\ \mu\text{s}$  wait, all circuit blocks are completely powered up internally. This  $10\ \mu\text{s}$  wait does not include the frequency settling time associated with the loop filter bandwidth.
8. Toggling the CE pin level causes the ADF4383 to return to full power-down mode and return the SPI registers to the POR state (see Step 2 and Step 3).

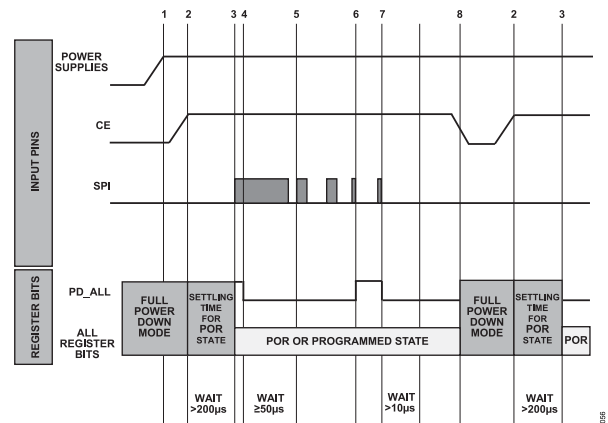

Figure 62. Power-Up and Initialization

## Programming Procedure

There are two different methods to power up the ADF4383. The most commonly used method is provided in the [Standard Power-Up and Initialization Sequence](#). Automatic VCO Calibration section is mandatory at the initial device power-up.

The method provided in the [Fast Power-Up and Initialization, Manually Programmed VCO Calibration Settings](#) section is an optional power-up procedure after the initial power-up.

## APPLICATIONS INFORMATION

**Standard Power-Up and Initialization Sequence, Automatic VCO Calibration**

The following standard power-up and initialization sequence is the recommended procedure to power up and program the ADF4383:

1. Follow Step 1 through Step 5 in the [Power-Up and Initialization Sequence](#) section.
2. It is optional to monitor the status of the VCO calibration bits, ADC\_BUSY and FSM\_BUSY (Register 0x058, Bit 2 and Bit 1, respectively). A VCO calibration is completed when ADC\_BUSY transitions from high to low followed by FSM\_BUSY transitioning from high to low.
3. After the VCO calibration is complete, disable the VCO calibration clocks by setting EN\_DRCLK = EN\_DNCLK = EN\_ADC\_CLK = 0. Disabling the VCO calibration clocks reduces unwanted spurious content.
4. The PLL is locked when the lock detector sets the LKDET pin (Pin 27) and the LOCKED bit (Register 0x58, Bit 0) high.
5. When changing the frequency, take the following steps:
  - a. Program only the modified registers.
  - b. Write to Register 0x010 to start a new VCO autocalibration as the final step whether it is modified or not.

**Fast Power-Up and Initialization, Manually Programmed VCO Calibration Settings**

For fast frequency hopping applications, much shorter lock time is required. The ADF4383 can be manually programmed with predetermined calibration values to decrease overall lock time by bypassing VCO calibration. The calibration values are first obtained by performing an autocalibration and reading back the corresponding band, core, and bias values for a given frequency. These values can then be manually programmed to the ADF4383 on subsequent device initializations. The values of the readbacks vary with each device due to process variation.

The following steps outline the procedure to perform a manual VCO calibration after initialization:

1. Perform an autocalibration with the target frequency required.
2. Read back and record the VCO\_CORE and VCO\_BAND.
3. If VCO\_CORE = 0, read the VCO bias value from VCO0\_BIAS\_RDBK. If VCO\_CORE = 1, read the VCO bias value from VCO1\_BIAS\_RDBK. The value read is used as the M\_VCO\_BIAS value.
4. On subsequent power-up and initialization sequences, program the override (O\_VCO\_CORE, O\_VCO\_BAND, and O\_VCO\_BIAS) and manual VCO bits (M\_VCO\_CORE, M\_VCO\_BAND, and M\_VCO\_BIAS) as documented in [Table 24](#).
5. Program fractional N-divider bit field values as required. See [Output Frequency](#) for calculation.

6. Program N\_INT value (Register 0x010) to program all manually calibrated values.
7. Repeat the sequence for each target frequency.

**Note:** When going from an integer to a fractional (or fractional to integer) RF output frequency, after the N\_INT register has been written to, MUTE\_NCLK must be set to 1 and then to 0.

**Table 24. Manually Programmed VCO Calibration Settings**

Bit Fields	Value	Description
O_VCO_DB	0x1	Manually calibrated values are double buffered by programming N_INT.
EN_AUTOCAL	0x0	Disables autocalibration.
EN_DRCLK	0x0	Disables DIV_RCLK to the digital block.
EN_DNCLK	0x0	Disables DIV_NCLK to the digital block.
EN_ADC_CLK	0x0	Disables the ADC clock.
O_VCO_CORE	0x1	Overrides the VCO core with value in M_VCO_CORE.
O_VCO_BAND	0x1	Overrides the VCO band with M_VCO_BAND.
O_VCO_BIAS	0x1	Overrides the VCO bias with M_VCO_BIAS.
M_VCO_CORE	Program with recorded values	Selects the VCO core when O_VCO_CORE = 1.
M_VCO_BAND	Program with recorded values	Selects the band within the core when O_VCO_BAND = 1.
M_VCO_BIAS	Program with recorded values	Selects the bias value used when O_VCO_BIAS = 1.
N_INT	N-divider integer word	Programs the double buffered manually calibrated values when written.
MUTE_NCLK	0x1	Mutes the clock signal from the N-divider block to the PFD. MUTE_NCLK must only be set to 1 and then to 0 when going from an integer to a fractional frequency or fractional to integer frequency.

## APPLICATIONS INFORMATION

## Fast Calibration

The fast calibration feature enables a VCO calibration time of <2  $\mu$ s for each output frequency change, by storing 32 discrete VCO core, band, and bias values across the octave range of the ADF4383. Fast calibration can be initiated during device initialization. When fast calibration is started, autocalibration is performed at 32 output frequencies across the octave output frequency range of the ADF4383. An on-chip look-up table in the device register map is used to store the corresponding VCO core, band, and bias value for each output frequency.

After initialization, subsequent output frequency changes utilize the previously stored look-up table to determine the optimal VCO calibration values by interpolation. Fast calibration is a more efficient alternative solution to manually programming VCO calibration settings, which requires an external microcontroller with memory storage. It also reduces the number of SPI writes required at each output frequency compared to manually writing. This feature is particularly useful in applications requiring many frequency hops.

## LOOP FILTER DESIGN

A stable loop filter design requires care in selecting the loop filter components of the ADF4383. It is recommended to download and install ADIsimPLL for loop filter design and simulation. ADIsimPLL has an integrated tutorial for first time users and a help manual for more complex topics. There are also several ADIsimPLL training videos available on the ADIsimPLL web page. After a loop filter is designed and simulated, it is recommended to verify the new loop filter using the ADF4383 evaluation hardware. A full loop filter design tutorial is beyond the scope of this data sheet. However, some best practices are shown in the following list. ADIsimPLL aids in defining and simulating these parameters. Any significant change to these items requires a new loop filter design.

A stable loop filter must meet the following criteria:

- ▶ Loop filter phase margin > 45°
- ▶ Loop filter bandwidth <  $f_{\text{PFD}} \div 10$

The desired loop filter bandwidth is determined by the following features of the ADF4383:

- ▶  $I_{\text{CP}}$
- ▶  $K_{\text{VCO}}$
- ▶ PFD frequency
- ▶ Reference input phase noise (see the [Reference Phase Noise](#) section)
- ▶ Trade-off between minimizing jitter or settling time

The VTUNE pin has an internal 54 pF capacitor to GND that must be included in the loop filter design. ADIsimPLL takes this internal capacitance into account automatically.

Another consideration when selecting the loop filter components is the largest value capacitor in the loop filter design because this will

directly affect the minimum VTUNE precharge time before a VCO calibration. The minimum precharge time is calculated as follows:

$$t_{\text{PRECHARGE}} = \frac{C \times V}{I} \quad (21)$$

where:

$I$  is the VCO calibration generator current (6 mA).

$C$  is the largest loop filter capacitance.

$V$  is the nominal charge pump voltage.

For example, using a capacitance value of 10 nF and charge pump voltage of 3.6 V results in the following:

$$t_{\text{PRECHARGE}} = \frac{10 \text{ nF} \times 3.6 \text{ V}}{6 \text{ mA}} = 6 \mu\text{s}$$

Refer to the [VCO Calibration](#) section for programming the pre-charge time dependent bit fields.

## REFERENCE SOURCE CONSIDERATIONS

## Reference Input Network

The reference input buffer of the ADF4383 shown in [Figure 46](#) provides a flexible interface to either differential or single-ended frequency sources. [Figure 63](#) to [Figure 68](#) show the recommended interfaces for different reference signal types. All characteristic impedance ( $Z_0$ ) signal traces are 50  $\Omega$  transmission lines.

Figure 63. Single-Ended 50  $\Omega$  Source ( $V_{\text{REF}} < 2.6 \text{ V p-p}$ )

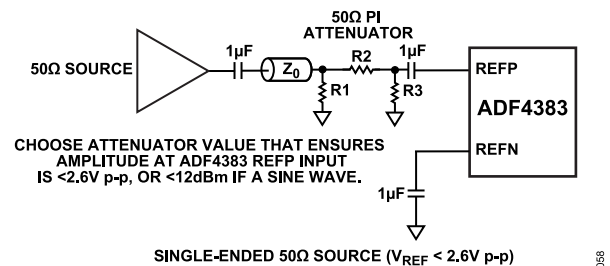

Figure 64. Single-Ended 50  $\Omega$  Source ( $V_{\text{REF}} < 2.6 \text{ V p-p}$ )

## APPLICATIONS INFORMATION

Figure 65. Single-Ended CMOS (R<sub>SER</sub> Is the Series Resistance.)

Figure 66. Differential, Low Voltage, Positive Emitter-Coupled Logic (LVPECL)

Figure 67. Differential LVDS

Figure 68. Differential CML

## Reference Phase Noise

The ADF4383 achieves an in-band normalized phase noise floor of  $L_{NORM} = -239$  dBc/Hz in integer mode and  $L_{NORM} = -237$  dBc/Hz in fractional mode.

To calculate the equivalent input phase noise floor ( $L_{IN}$ ) use the following formula:

$$L_{IN} = L_{NORM} + 10 \times \log_{10}(f_{REF}) \quad (22)$$

For example, a 100 MHz reference input frequency gives an  $L_{IN}$  of  $-157$  dBc/Hz in fractional mode. The phase noise of the reference frequency source must be at least 6 dB less than  $L_{IN}$  to avoid impacting and increasing the overall system phase noise.

To maintain typical  $L_{NORM}$  performance, Table 7 provides criteria for selecting the optimal REF\_SEL (Register 0x030, Bit 5) setting based on the input reference signal type and amplitude.

## SYNC INPUT NETWORK

The SYNC input pins may be programmed for CML/LVPECL or LVDS interfaces using the SYNC\_SEL bit to support a range of input SYNC signal levels. Figure 69 to Figure 72 show recommended input networks to SYNC input pins.

Figure 69. DC-Coupled Differential CML (Set SYNC\_SEL = 0)

Figure 70. DC-Coupled Differential LVPECL (Set SYNC\_SEL = 0)

Figure 71. DC-Coupled Differential LVDS (Set SYNC\_SEL = 1)

Figure 72. DC-Coupled 3.3 V Single-Ended Logic to LVDS Input (Set SYNC\_SEL = 1)

## OUTPUT PHASE NOISE CHARACTERISTICS

## In-Band Output Phase Noise

Use the following equations to calculate the in-band phase noise floor ( $L_{OUT}$ ) produced at  $f_{OUT}$ :

## APPLICATIONS INFORMATION

$$L_{OUT} = L_{NORM} + 10 \times \log_{10}(f_{PFD}) + 20 \times \log_{10}\left(\frac{f_{OUT}}{f_{PFD}}\right) \quad (23)$$

or

$$L_{OUT} = L_{NORM} + 10 \times \log_{10}(f_{PFD}) + 20 \times \log_{10}\left(\frac{N}{O}\right) \quad (24)$$

## Output Phase Noise Due to 1/f Noise

In-band phase noise at low offset frequencies can be influenced by the 1/f noise of the ADF4383 depending on the  $f_{PFD}$ . Use the normalized in-band 1/f noise ( $L_{1/f}$ ) of -287 dBc/Hz to approximate the output 1/f phase noise at a given frequency offset ( $f_{OFFSET}$ ) as follows:

$$L_{OUT(1/f)} = L_{1/f} + 20 \times \log_{10}(f_{OUT}) - 10 \times \log_{10}(f_{OFFSET}) \quad (25)$$

Unlike the in-band noise floor ( $L_{OUT}$ ), the 1/f noise ( $L_{OUT(1/f)}$ ) does not change with  $f_{PFD}$  and is not constant over offset frequency. For an example of in-band phase noise for  $f_{PFD}$  equal to 100 MHz and 500 MHz for integer mode, see Figure 73. The total phase noise is the summation of  $L_{OUT}$  and  $L_{OUT(1/f)}$  calculated by the following formula:

$$L_{OUT(TOTAL)} = 10 \times \log_{10}\left(10^{L_{OUT}/10} + 10^{L_{OUT(1/f)}/10}\right) \quad (26)$$

Figure 73. Theoretical In-Band Phase Noise,  $f_{OUT} = 10$  GHz

## OUTPUT PHASE SYNCHRONIZATION OF MULTIPLE ADF4383 DEVICES

To synchronize multiple ADF4383 devices, use one of the following two methods:

- EZSync™ method, which uses SPI register writes for synchronization

- Timed synchronization method, which uses the SYNCx pin on the ADF4383 for synchronization

## EZSync Method

The EZSync synchronization method allows synchronization of the output phases of multiple devices without the need for a separate synchronization signal, which has the advantage of reducing PCB layout complexity in systems using multiple ADF4383 devices.

EZSync relies on sending a synchronization request through the SPI by setting SW\_SYNC = 1 instead of the SYNC pin. The problem with sending the request over the SPI is that the SPI is a slow protocol and does not have any time accuracy. Sending the request in the same reference period is also another challenge and not possible for the large number of ADF4383 devices used. With EZSync, these problems are solved by starting and stopping the DC-coupled reference signal glitchlessly, which removes the setup and hold time concerns with sending a request through the SPI. The reference signals must stop and start accurately and without any glitch or without any runt pulse. The clock generation and distribution devices from Analog Devices, such as the HMC7044B, are recommended as these devices are compatible with EZSync.

The following steps outline the procedure to perform an EZSync with two ADF4383 devices (assumes the hardware is set up as per Figure 74):

- Set up the HMC7044B for EZSync configuration as follows:
  - Set the channel that is used as a reference to the ADF4383 to dynamic mode. For example, for Channel 0, set Register 0x00C8 to 0xFF.
  - Set the output driver mode of the channel to LVPECL or CML and set the mute select of the channel to 0. For example, set Register 0x00D0 = 0x89.
  - Set the pulse generator mode selection to continuous mode by setting Register 0x005A to 0x07.
  - Send a reseed request to start the references by setting the reseed request to 1 and then 0 by setting Register 0x001 to 0x80 then setting to 0x00.
- Set up each ADF4383 as follows:
  - Initialize the ADF4383 with the default initialization settings.
  - Set TIMED\_SYNC = 0.
  - Set EN\_REF\_RST = 1.
  - Set EN\_PHASE\_RESYNC = 1.
  - Set SYNC\_SEL = 1.
- Verify that both ADF4383 devices are locked.
- Synchronize both ADF4383 RFOUT signals:
  - On an oscilloscope, first verify that both ADF4383 parts are not synchronized.
  - Set SW\_SYNC = 1 on each ADF4383.
  - Set Pulse Generator Mode Selection to 0 to stop the reference on the HMC7044B (set Register 0x005A to 0x00).

## APPLICATIONS INFORMATION

- d. Set Pulse Generator Mode Selection to 7 on the HMC7044B (set Register 0x005A to 0x07).
  - e. Send a pulse request by setting Register 0x0001 to 0x04 then 0x0 to restart the reference.
  - f. Set SW\_SYNC = 0 on each ADF4383.
5. On the oscilloscope, verify that the outputs from both ADF4383 devices are synchronized (aside from cable mismatch).

Figure 74. EZSync Configuration

## Timed Synchronization Method

The timed synchronization method uses an external synchronization signal to synchronize multiple ADF4383 devices, which is the more traditional method for synchronization of devices. This method requires an additional external signal from the clock distribution device to provide the synchronization signal. Each synchronization signal must be matched for accurate output phase matching. A rising edge of the synchronization pulse on the SYNC pin of the ADF4383 triggers the start of the synchronization process, which then puts the device into a reset state. On the falling edge of the synchronization pulse, the RFOUT signal phase on each ADF4383 is then aligned to a known phase relative to the reference phase.

The following steps outline the procedure to perform a timed synchronization with two ADF4383 devices in the configuration shown in Figure 75:

1. Set up the HMC7044B as follows:
  - a. Set the channels used as a reference to the ADF4383 to asynchronous mode (for example, set Register 0x00C8 to 0xF3 for Channel 0).
  - b. Set the divider ratio of the reference channels to 16 for a reference frequency of 250 MHz (for example, set Register 0x00C9 for Channel 0).
  - c. Set the channels used as a SYNC signal to the ADF4383 to dynamic mode (for example, set Register 0x00D2 to 0xFF).
  - d. Set the divider ratio of the SYNC channels to 8.
  - e. Set the SYSREF timer (Register 0x005B and Register 0x005C) value of the HMC7044B the same as the divider value of the SYNC channels.
  - f. Set the pulse mode selection to pulse (set Register 0x005A to 0x01).

- g. Send a reseed request to start the references by setting the reseed request to 1 and then 0 by setting Register 0x001 to 0x80 then setting to 0x00.

## 2. Set up the ADF4383 as follows:

- a. Set TIMED\_SYNC (Register 0x01E, Bit 5) = 1.
- b. Set EN\_REF\_RST (Register 0x01E, Bit 6) = 1.
- c. Set EN\_PHASE\_RESYNC (Register 0x01E, Bit 7) = 1.
- d. Set SYNC\_SEL (Register 0x053, Bit 5) = 0.
- e. Set R\_DIV (Register 0x020, Bits[5:0]) = 4.
- f. Set EN\_DRCLK (Register 0x02D, Bit 6) = 1.
- g. Verify that the ADF4383 devices are locked.

## 3. Synchronize both ADF4383 devices as follows:

- a. Verify that both ADF4383 outputs are not synchronized.
- b. Send a pulse generator request to the HMC7044B by toggling Register 0x001 data from 0x04 to 0x00.
- c. Verify that both outputs on both ADF4383 devices is now phase synchronized.

Figure 75. Timed Synchronization Configuration

## APPLICATIONS INFORMATION

## PHASE SYNCHRONIZATION SETTINGS

To optimize phase noise and spurious performance on the ADF4383, there are a number of bit fields that must be program-

med based on the  $f_{\text{PFD}}$  used. [Table 25](#) shows the optimal settings for phase synchronization.

**Table 25. Phase Synchronization Settings**

PFD Frequency	RDIV = 3, 6, 12, 14, 15, 24, 26 to 31, 46, 48 to 63			RDIV = 1, 2, 4, 5, 7 to 11, 13, 16 to 23, 25, 32 to 45, 47		
	REF_CK_FALL	REF_DC_SEL	xx_DEL <sup>1</sup>	REF_CK_FALL	REF_DC_SEL	xx_DEL <sup>1</sup>
$f_{\text{PFD}} \geq 225 \text{ MHz}$	0	0	3	0	0	3
$200 \text{ MHz} \leq f_{\text{PFD}} < 225 \text{ MHz}$	0	0	4	0	0	4
$148 \text{ MHz} \leq f_{\text{PFD}} < 200 \text{ MHz}$	1	3	1	1	3	0
$130 \text{ MHz} \leq f_{\text{PFD}} < 148 \text{ MHz}$	1	3	3	1	3	1
$85 \text{ MHz} \leq f_{\text{PFD}} < 130 \text{ MHz}$	1	3	4	1	3	1
$f_{\text{PFD}} < 85 \text{ MHz}$	1	2	0	1	2	1

<sup>1</sup> xx\_DEL denotes SYNC\_DEL, DNCLK\_DEL, and DRCLK\_DEL.

## APPLICATIONS INFORMATION

## PHASE RESYNCHRONIZATION

Phase resynchronization is a feature that allows a consistent phase on the RFOUT signal with respect to the input reference at each output frequency, which is useful in applications requiring synchronization of multiple ADF4383 devices. After multiple devices are synchronized, any additional resynchronizing (for example, after a frequency change) is not needed. When phase resynchronization is used, the maximum value for MOD2WORDMAX is  $= 2^{17} - 1 = 131071$ . Refer to [Output Frequency](#) section for MOD2WORDMAX calculation.

The following sequence is the phase resynchronization method procedure:

1. Power up and initialize the ADF4383 devices.
2. Program all ADF4383 devices to the same frequency.
3. Perform an initial synchronization (see the [Timed Synchronization Method](#) section or the [EZSync Method](#) section for additional information).
4. Enable phase resynchronization mode by taking the following steps:
  - a. Set DEL\_MODE (Register 0x032, Bit 5) = 1.
  - b. Set EN\_PHASE\_RESYNC (Register 0x01E, Bit 7) = 1.
  - c. Set EN\_REF\_RST (Register 0x01E, Bit 6) = 0.
  - d. Set EN\_DRCLK (Register 0x02D, Bit 6) = 1.
  - e. Program the  $t_{RESYNC}$  default to 100  $\mu$ s by

$$t_{RESYNC} = \frac{RESYNC\_WAIT}{f_{PFD}} \quad (27)$$

for  $f_{PFD} = 250$  MHz and  $t_{RESYNC} = 25,000$ .

Note that when using fast power-up and initialization, manually programmed VCO calibration settings (see the [Fast Power-Up and Initialization, Manually Programmed VCO Calibration Settings](#) section), MUTE\_NCLK must be set to 1 after going from integer to fractional RF output frequencies (or vice versa). In this case, phase resynchronization is not maintained each time MUTE\_NCLK is set to 1 after a frequency change.

## REGISTER DETAILS

Address: 0x000, Reset: 0x00, Name: REG0000

Table 27. Bit Descriptions for REG0000

Bits	Bit Name	Description	Reset	Access
7	SOFT_RESET_R	Repeat of SOFT_RESET.	0x0	R/W
6	LSB_FIRST_R	Repeat of LSB_FIRST.	0x0	R/W
5	ADDRESS_ASCENSION_R	Repeat of ADDRESS_ASCENSION.	0x0	R/W
4	SDO_ACTIVE_R	Repeat of SDO_ACTIVE.	0x0	R/W
3	SDO_ACTIVE	Choose Between 3-Wire or 4-Wire Operation. 0: 3-wire. 1: 4-wire SPI (enables SDO and SDIO becomes an input only).	0x0	R/W
2	ADDRESS_ASCENSION	Address Ascension When Streaming. 0: address auto-decrements when streaming.	0x0	R/W

## REGISTER MAP

Table 27. Bit Descriptions for REG0000 (Continued)

Bits	Bit Name	Description	Reset	Access
1	LSB_FIRST	1: address auto-increments when streaming. I/O Data Oriented LSB First. 0: MSB first. 1: LSB first.	0x0	R/W
0	SOFT_RESET	Reset SPI Registers Except REG0000 to POR State. Self-Clearing Reset 0: normal operation. 1: soft reset.	0x0	R/W

Address: 0x001, Reset: 0x00, Name: REG0001

Table 28. Bit Descriptions for REG0001

Bits	Bit Name	Description	Reset	Access
7	SINGLE_INSTRUCTION	Single Instruction. 0: SPI streaming enabled. 1: SPI streaming disabled.	0x0	R/W
6	REG01_RSV6	Reserved. The ADF4383 register map provides reserved register settings.	0x0	R/W
5	MAIN_READBACK_CONTROL	Main/Subordinate Readback Control. 0: For double buffered bit fields readback subordinate register. 1: For double buffered bit fields readback main register.	0x0	R/W
4	REG01_RSV4	Reserved. The ADF4383 register map provides reserved register settings.	0x0	R/W
3	RESERVED	Reserved.	0x0	R
2	REG01_RSV1	Reserved. The ADF4383 register map provides reserved register settings.	0x0	R/W
1	REG01_RSV0	Reserved. The ADF4383 register map provides reserved register settings.	0x0	R/W
0	RESERVED	Reserved.	0x0	R

Address: 0x003, Reset: 0x00, Name: REG0003

Table 29. Bit Descriptions for REG0003

Bits	Bit Name	Description	Reset	Access
[7:4]	RESERVED	Reserved.	0x0	R
[3:0]	CHIP_TYPE	Chip Type = 0x06.	0x0	R

Address: 0x004, Reset: 0x00, Name: REG0004

Table 30. Bit Descriptions for REG0004

Bits	Bit Name	Description	Reset	Access
[7:0]	PRODUCT_ID[7:0]	Product ID = 0x0008.	0x0	R

Address: 0x005, Reset: 0x00, Name: REG0005
