DG411F/DG412F/ DG413F

Quad, Rail-to-Rail, Fault-Protected, SPST Analog Switches

General Description

The DG411F/DG412F/DG413F are quad, single-pole/single-throw (SPST), fault-protected analog switches. They are pin compatible with the industry-standard nonprotected DG411/DG412/DG413. These new switches feature fault-protected inputs and Rail-to-Rail® signal-handling capability. All terminals are protected from overvoltage faults up to $\pm 36\text{V}$ with power on and up to $\pm 40\text{V}$ with power off. During a fault condition, the COM, NO, or NC terminal becomes an open circuit and only microamperes of leakage current flow from the source. On-resistance is 35Ω (max) and is matched between switches to 1.5Ω (max) at $+25^\circ\text{C}$.

The DG411F has four normally closed (NC) switches. The DG412F has four normally open (NO) switches. The DG413F has two NC and two NO switches. These CMOS switches operate with dual power supplies ranging from $\pm 4.5\text{V}$ to $\pm 20\text{V}$ or a single supply between $+9\text{V}$ and $+36\text{V}$. All digital inputs have $+0.8\text{V}$ and $+2.4\text{V}$ logic thresholds, ensuring both TTL and CMOS logic compatibility when using $\pm 15\text{V}$ or a single $+12\text{V}$ supply.

For supply voltages of $\pm 5\text{V}$, $+5\text{V}$, and $+3\text{V}$, refer to the MAX4711/MAX4712/MAX4713 data sheet.

Applications

- Communication Systems
- Signal Routing
- Test Equipment
- Data Acquisition
- Industrial and Process Control Systems
- Avionics
- Redundant/Backup Systems

Benefits and Features

- No Power-Supply Sequencing Required
- Rail-to-Rail Signal Handling
- All Switches Off with Power Off
- All Switches Off when V_+ is Off and V_- is On
- $\pm 40\text{V}$ Fault Protection with Power Off
- $\pm 36\text{V}$ Fault Protection with $\pm 15\text{V}$ Supplies
- Control Line Fault Protection from $V_- - 0.3\text{V}$ to $V_- + 40\text{V}$
- Pin Compatible with Industry-Standard DG411/DG412/DG413
- 20ns (typ) Fault Response Time
- 35Ω (max) R_{ON} with $\pm 15\text{V}$ Supplies
- $\pm 4.5\text{V}$ to $\pm 20\text{V}$ Dual Supplies
- $+9\text{V}$ to $+36\text{V}$ Single Supply
- TTL- and CMOS-Compatible Logic Inputs with $\pm 15\text{V}$ or Single $+9\text{V}$ to $+15\text{V}$ Supplies

Ordering Information appears at end of data sheet.

Rail-to-Rail is a registered trademark of Nippon Motorola, Ltd.

Absolute Maximum Ratings

(Voltages Referenced to GND)

V+	-0.3V to +44V	Peak Current COM_, NO_, NC_ (pulsed at 1ms, 10% duty cycle)	±100mA
V-	-44V to +0.3V	Continuous Power Dissipation (T _A = +70°C)	
V+ to V-	-0.3V to +44V	16-Pin TSSOP (derate 9.4mW/°C above +70°C)	755mW
IN_	(V- - 0.3V) to (V- + 40V)	16-Pin SO (derate 8.7mW/°C above +70°C)	696mW
NO_, NC_ to COM_ (Note1)	-40V to +40V	16-Pin Plastic DIP (derate 10.53mW/°C above +70°C)	842mW
COM_, NO_, NC_ Voltage with Power On (Note 1)	-36V to +36V	Operating Temperature Range	-40°C to +85°C
COM_, NO_, NC_ Voltage with Power Off (Note 1)	-40V to +40V	Junction Temperature	+150°C
Continuous Current (any terminal)	±30mA	Storage Temperature Range	-65°C to +160°C
		Lead Temperature (soldering, 10s)	+300°C

Note 1: COM_, NO_, and NC_ pins are fault protected. Signals on COM_, NO_, and NC_ exceeding -36V to +36V may damage the device during power-on conditions. When the power is off, the maximum range is -40V to +40V.

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Package Information

PACKAGE TYPE: SOIC	
Outline Number	21-0041
PACKAGE TYPE: PDIP	
Outline Number	21-0043
PACKAGE TYPE: TSSOP	
Outline Number	21-0066

For the latest package outline information and land patterns (footprints), go to www.maximintegrated.com/packages. Note that a "+", "#", or "-" in the package code indicates RoHS status only. Package drawings may show a different suffix character, but the drawing pertains to the package regardless of RoHS status.

Detailed Description

The DG411F/DG412F/DG413F are fault-protected CMOS analog switches with unique operation and construction. These switches differ considerably from traditional fault-protection switches, with several advantages. First, they are constructed with two parallel FETs, allowing very low on-resistance when the switch is on. Second, they allow signals on the NO_ or NC_ pins that are within, or slightly beyond, the supply rails to be passed through the switch to the COM_ terminal (or vice versa), allowing true rail-to-rail signal operation. Third, the DG411F/DG412F/DG413F have the same fault-protection performance on any of the NO_, NC_, or COM_ switch inputs. Operation is identical for both fault polarities. The fault protection extends to ±36V from GND with ±15V supplies.

During a fault condition, the particular overvoltage input (COM_, NO_, NC_) pin becomes high impedance regardless of the switch state or load resistance. When power is removed, the fault protection is still in effect. In this case, the COM_, NO_, or NC_ terminals are a virtual open circuit. The fault can be up to ±40V with power off. The switches turn off when V+ is not powered, regardless of V-.

Pin Compatibility

These switches have identical pinouts to common non-fault-protected CMOS switches. They allow for carefree direct replacement in existing printed circuit boards since the NO_, NC_, and COM_ pins of each switch are fault protected.

Internal Construction

Internal construction is shown in Figure 1, with the analog signal paths shown in bold. A single NO switch is shown. The NC configuration is identical except the logic-level translator becomes an inverter. The analog switch is formed by the parallel combination of N-channel FET (N1) and P-channel FET (P1), which are driven on and off simultaneously according to the input fault condition and the logic-level state.

Normal Operation

Two comparators continuously compare the voltage on the COM_, NO_, and NC_ pins with V+ and V-. When the signal on COM_, NO_, or NC_ is between V+ and V-, the switch acts normally, with FETs N1 and P1 turning on and off in response to IN_ signals. The parallel combination of N1 and P1 forms a low-value resistor between NO_ (or NC_) and COM_ so that signals pass equally well in either direction.

Positive Fault Condition

When the signal on NO_ (or NC_) and COM_ exceeds V+ by about 50mV, the high-fault comparator output is high, turning off FETs N1 and P1. This makes the NO_ (or NC_) and COM_ pins high impedance regardless of the switch state. If the switch state is off, all FETs are turned off and both NO_ (or NC_) and COM_ are high impedance.

Negative Fault Condition

When the signal on NO_ (or NC_) and COM_ exceeds V- by about 50mV, the low-fault comparator output is high, turning off FETs N1 and P1. This makes the NO_ (or NC_) and COM_ pins high impedance regardless of the switch state. If the switch state is off, all FETs are turned off and both NO_ (or NC_) and COM_ are high impedance.

Transient Fault Response and Recovery

When a fast rise-time and fall-time transient on NO_, NC_, or COM_ exceeds V+ or V-, the output follows the input to the supply rail with only a few nanoseconds delay. This delay is due to the switch on-resistance and circuit capacitance to ground. When the input transient returns to within the supply rails, however, there is a longer output recovery time delay. For positive faults, the recovery time is typically 1μs. For negative faults, the recovery time is typically 0.5μs. These values depend on the output resistance and capacitance, and are not production tested or guaranteed. The delays are not dependent on the fault amplitude. Higher load resistance and capacitance increase recovery times.

Fault-Protection Voltage and Power Off

The maximum fault voltage on the NO_ (or NC_) and COM_ pins is ±36V with power applied and ±40V with power off.

Failure Modes

Exceeding the fault-protection voltage limits on NO_, NC_, or COM_, even for very short periods, can cause the device to fail. See the Absolute Maximum Ratings. The failure modes may not be obvious, and failure in one switch may or may not affect other switches in the same package.

Ground

There is no galvanic connection between the analog signal paths and GND. The analog signal paths consist of an N-channel and P-channel MOSFET with their sources and drains paralleled and their gates driven out of phase to V+ and V- by the logic-level translators. However, the potential of the analog signals must be defined or at least limited with respect to GND. V+ and GND power the internal logic and logic-level translators and set the input logic thresholds. The logic-level translators convert the logic levels to switched V+ and V- signals to drive the gates of the analog switches. This drive signal is the only connection between the power supplies and the analog signals.

IN_ Logic-Level Thresholds

The logic-level thresholds are CMOS and TTL compatible when V+ is +15V. As V+ is raised, the threshold increases slightly, and when V+ reaches 25V, the level threshold is about 2.3V, above the TTL output high-level minimum of 2.4V, but still compatible with CMOS outputs (see the *Typical Operating Characteristics*). V- has no effect on the logic-level thresholds.

Bipolar Supplies

The DG411F/DG412F/DG413F operate with bipolar supplies between ±4.5V and ±20V. The V+ and V- supplies need not be symmetrical, but their difference cannot exceed the absolute maximum rating of 44V.

Single Supply

The DG411F/DG412F/DG413F operate from a single supply between +9V and +36V when V- is connected to GND.

ESD DIODE

The diagram illustrates the electrical characteristics of the DG411F, DG412F, and DG413F CMOS transmission gates. On the left, a circuit diagram shows the device connected as a switch. The input signal $V_{IN_}$ is applied to the $NO_OR\ NC_$ pin. The $V+$ pin is connected to a positive supply voltage $V+$, and the $V-$ pin is connected to ground (GND). The output V_{OUT} is taken from the $COM_$ pin, which is connected to a load resistor R_L and a load capacitor C_L . The $V+$ pin is also labeled $V+$ and the $V-$ pin is labeled $V-$. The device is labeled **DG411F**, **DG412F**, and **DG413F**.

On the right, a timing diagram shows the input voltage $V_{IN_}$ and the output voltage V_{OUT} over time. The input $V_{IN_}$ is a square wave switching between 0V and 3V. The output V_{OUT} is a square wave switching between 0V and 10V. The diagram indicates the 50% and 90% voltage levels for both input and output. The output transition times are labeled t_{OFF} (turn-off time) and t_{ON} (turn-on time).

$V-$ IS CONNECTED TO GND (0V) FOR SINGLE-SUPPLY OPERATION.
